

What is on you

1

One thing. About five minutes.

Create an API token in Jira and paste it into a file. That is the whole list.

You asked for your engagement to be as small as possible, and once if it could be. It can. Everything else in this programme either does not need you, or waits on that one token.

Why it is only one thing now

You told me the organisation list is already in Jira. That removes the spreadsheet from your list entirely — once I can read Jira, I take the list from there and build the real map myself. And you are giving me real email addresses later, so handing out passwords is not part of this either.

Before you turn the page — something you should know

I re-checked your live database rather than trusting my own notes, and found something that changes what matters. **Everything on the map today is invented.** The next page is that check, in full. It is not bad news — the software is finished and working. It is that the software has never been given anything real to show.

What is actually in your workspace right now

I read this straight out of the live database on 22 August, not from any document. Documents drift; this does not.

Organisations on the map	85 — every one invented. “Anwa Polyclinic”, “Bareq Specialist Polyclinic”, sitting under “Account Book One” and “Associate Directorate Alpha”. None of these exist.
Your real tree, 0B	Empty. Nothing has ever been put in it.
People who have signed in	2 of 18. You, and Nasser. The other sixteen have never opened it.
Their email addresses	Made-up ones ending @opstrack.internal, so the system cannot send them anything.
Jira connection	Never set up. The settings table is empty.
The software itself	Finished, deployed, 5,384 automated checks passing.

What this means in one sentence

If Ahmed Alnaji opened the map this afternoon, he would see a tidy, working application showing him **a list of clinics that do not exist**. No feature I add changes that. Only real data does.

And why that is the good version of this news

The hard part — the software — is done. What is left is filling it, and the filling is one token away because your list is already in Jira.

What these words mean

Nothing later uses a term that is not on this page.

API token

sometimes “API key”

A long password that a *program* uses instead of a person. It lets my code sign in to Jira as you, and read what you can read. It cannot be typed by a human at a login screen, and it can be cancelled at any time without changing your own password.

Scoped

A token that is limited to certain things — here, **reading** only. It is the only kind your Atlassian account can create, and it is the safer kind. I have already built the code to work with it.

Read-only

The token I am asking for can **look** at Jira and change nothing in it. Nothing I do can move a ticket, close an issue or notify anyone.

Function secret

Where the token goes to live afterwards: a locked box on the server, readable by the running code and by nobody through a browser. I put it there; you never have to.

Cloud ID

Jira’s internal number for your Atlassian site. You will never see or type it — my code looks it up. Mentioned only because it appears in the technical notes.

One rule, and it is the only rule

Never paste the token into a chat window — including mine. Anything typed in a chat is stored in that conversation. The token goes into a file, and I read the file. Page 5 is that file.

1

Create the token

In your browser, signed in to Atlassian as yourself. About three minutes.

1

Go to `id.atlassian.com/manage-profile/security/api-tokens`

You land on a page headed **API tokens**, probably with an empty list.

2

Press the button that creates a token.

Atlassian keeps changing this wording — it may say **Create API token**, or offer you a choice between a plain one and one “with scopes”. **If you are offered the choice, take the one with scopes.** It is the only kind your account can make.

A small form appears asking for a name.

3

Name it `nphiescore` and set the longest expiry it offers you.

The name is only a label so you can recognise it later and cancel it if you ever want to.

4

If it asks which app, choose **Jira**. If it then asks which permissions, tick the two that mention **reading work** and **reading user** — usually shown as `read:jira-work` and `read:jira-user`.

Nothing on that list should say **write**, **manage** or **delete**. If you ticked one by accident, untick it — I do not need it.

5

Create it, then **copy the token**.

A long string of letters and numbers appears.

This is the trap, and everyone hits it once

The token is shown exactly once. Close that window without copying it and it is gone for good — there is no “show it again”. You are not locked out if that happens: delete the token you just made and create another. It costs two minutes, not a support ticket.

Three lines. I will have the file open and waiting, so you are filling in blanks, not creating anything.

JIRA_BASE_URL

Your Jira web address, as far as .net and no further. Looks like `https://something.atlassian.net` — copy it out of your browser's address bar while Jira is open, then delete everything after .net.

.....

JIRA_EMAIL

The email address **you sign in to Atlassian with**. Not a colleague's, and not necessarily the one you use for everything else — it must be the account that made the token on the previous page.

.....

JIRA_API_TOKEN

The long string you copied. Paste it whole — no spaces before or after, no quotation marks.

.....

The mistake this step invites

Pasting the **whole Jira page address** into the first box — the one with `/jira/software/projects/...` on the end. The code checks for this and refuses with a clear message rather than failing strangely, so it is recoverable — but it costs a round trip. Stop at .net.

Then you are finished

Tell me the file is filled in. You do not need to press **Test connection** in the app — I can check it directly from my side, and I will tell you what I found.

What happens, and when

You do nothing further in any of this. It is here so you know what to expect and when to expect it.

Minutes

I put the three values into the server's locked box and **check the connection myself**. If anything is wrong with the token, this is where it surfaces — and I come back to you with the exact problem, not a shrug.

Within an hour

I read your Jira and tell you **plainly whether it holds enough to build the map from**. You said the list there is incomplete, so this is a real fork — and if it is too thin, I will say so rather than quietly building a half-map and calling it done.

Same day

Your **real organisations go into the map**, under 0B, with their stage where Jira knows it and **blank where it does not**. A blank means “nobody has said” and is left blank on purpose — the map never guesses a number.

Same day

The invented data — **Demo Slice** and **Demo Portfolio** — is deleted, as you asked. I keep a record that can restore it, so it is not a one-way door.

After that

The map shows **your programme**. That is the first moment it is worth putting in front of Ahmed Alnaji or Nawaf.

If Jira turns out to hold too little

Then — and only then — I come back with one spreadsheet, already filled in with your eighteen people and your seven real stage names, so that nothing you type into it can be rejected. That would be a second sitting. I would rather warn you it is possible than promise one and deliver two.

The one other thing, later

2

Real email addresses for your sixteen people.

No date on this. It does not block anything I am building.

Right now their accounts use invented addresses ending @opstrack.internal. Nothing can be delivered to those, which is why sixteen people have accounts they have never used.

Give me their real work addresses in any form — a list, a spreadsheet, a message — and **the system sends its own invitations**. Each person sets their own password. You never handle a password, and there is nothing to print or hand out.

Why this is worth waiting for rather than rushing

The alternative was me generating sixteen passwords for you to distribute on paper. That works, but it puts you in the middle of every one of them, and it means sixteen passwords exist on a sheet. Real addresses take you one message and remove the whole problem. This is the better trade, which is why it is second and not first.

Worth knowing

Two of the sixteen are the people this is being built for — **Nawaf Alharbi** (PMO Director) and **Ahmed Alnaji** (Executive Director, UHR). If you want to move only those two first, that is a perfectly good half-step, and I would suggest doing it on the day the real map lands rather than before.

Who does what

2

Yours, in total

- **The Jira token** — five minutes, now
- **Real email addresses** — one message, later

Neither can be done by me. The first because only you can create a token on your account; the second because only you know the addresses.

Mine

- Reading Jira and building the real map
- Deleting the invented data
- The PMO Dashboard — projects, initiatives, actions, risks, revenue, OKRs
- Making the map something you can work in, not just look at
- The Jira project picker in Settings
- Checking every one of the above in a real browser, in English and Arabic

What I am doing while I wait for the token

All of the right-hand column except the first two lines, which are the only ones that need Jira. So handing me the token late slows down the **map's contents** and nothing else — the PMO Dashboard is being built either way.

Tick these off

- ☐ Token created at `id.atlassian.com`, read-only, copied before the window closed
- ☐ Three lines filled into the file — address stops at `.net`
- ☐ Told me it is ready
- ☐ *Later:* real email addresses sent over
