

Your part

The map is being rebuilt as a proper tree you can configure, and a long list of features is going in behind it. Almost all of that is mine. **You have already done two of your six** — the stage names and the Jira connection. About forty minutes of yours remain.

~40 min

Still yours, across four sittings. The longest is twenty minutes; the next is five.

Hours

Mine, between your sittings. You do not need to be at the keyboard for any of it.

One thing is still switched off, and only you can switch it on

Checked against your live project just now:

✓ **All seven stages now have their Arabic name.** Done — the Arabic app reads as Arabic in the place that matters most.

✓ **Jira is connected.** Done, on a properly scoped read-only token.

✗ **All seven stages still have no “expected days”.** That is the documented off-switch for the at-risk count and the whole Stalled view — and about half the new features read from it. **Five minutes, and it is the last thing standing between you and a working portfolio.**

Step 2 is now the whole of your urgent list

Five minutes, on a screen you were on an hour ago. Everything else can wait until I ask.

When each thing happens

Purple is yours. Grey is mine and needs nothing from you.

✓ DONE

1 • Name your seven stages, in both languages.

All seven carry Arabic now.

NOW

2 • Say how long is too long on each rung. 5 min

The only thing left on your urgent list. Switches on at-risk, the Stalled view, and much of what is being built.

✓ DONE

3 • Make a read-only Jira token and set three secrets.

Connected, on a scoped read-only token. Field mapping comes later, with me.

WHENEVER

4 • Hand out the sixteen invite codes. 10 min

All eighteen accounts exist; only you and Nasser have ever signed in.

MINE

Rebuild the map as a vertical tree, make it configurable, and keep rendering it and looking at it until it is right. no input needed

THEN YOU

5 • Look at the new map and tell me what is wrong. 15 min

I will send you pictures first, then a link.

MINE

Fix what you named. Build the features behind it — search, saved views, trends, the programme forecast. no input needed

LAST

6 • The final walk-through, then say the word. 20 min

I publish it.

How long is the whole thing?

The new map itself is the first thing you will see, and it comes with pictures so you can judge it before it is anywhere near your live site. The features behind it land in waves after that, each one reviewable on its own.

Nothing goes live until step 6.

1

Name your seven stages

Ten minutes. In both languages, because Arabic is deliberately blank.

Scroll to the stages section. These are the seven rungs an organization climbs. They shipped with English placeholders and **no Arabic at all** — on purpose, because a guessed translation looks exactly like a reviewed one on screen, and nobody would ever catch it.

	ENGLISH — AS SHIPPED	ARABIC — YOURS TO WRITE
1	Not started	(empty)
2	Kickoff	(empty)
3	Integrating	(empty)
4	Testing/UAT	(empty)
5	Go-live ready	(empty)
6	Live	(empty)
7	Paused	(empty)

- 1

Change the English words to whatever your programme actually calls these stages. If CHI's five words are what people say out loud, use those.
- 2

Write the Arabic for each one.
- The screen marks the ones still untranslated, so you can see your progress.

Renaming is completely safe now

There was a window where renaming these would have caused trouble; it closed when you finished the four SQL files. Rename freely. **Two of them carry a meaning that is not their name**, and it follows the rung, not the word: one rung counts as *arrived* (currently **Live**) and one *stops the clock* (currently **Paused**). Rename them and the meaning goes with them.

2

Say how long is too long

Five minutes, same screen. This is the highest-value five minutes on your list.

Beside each rung there is a box called **expected days**. It means: *if an organization sits on this rung longer than this, something is wrong*. Every one of them is empty today.

While they are empty, these are all switched off

The **at-risk count** on the Portfolio button — permanently zero, which reads as “nothing is stuck”. The **Stalled view** — empty for every organization. The **longest-stuck-first ordering** — nothing to order by. And roughly half of the new features being built read from this number.

This is deliberate, not a bug: a threshold nobody chose is a number the app would start chasing your team with. **It waits for you to choose.**

	RUNG		DAYS
1	Not started	leave empty – no clock	–
2	Kickoff	how long should this take?	?
3	Integrating	usually the longest	?
4	Testing/UAT		?
5	Go-live ready	should be short	?
6	Live	arrived – leave empty	–
7	Paused	clock stops here anyway	–

Only the middle four need a number — and guessing is fine

Leaving one empty means **that rung has no clock**; nothing on it is ever called stuck. That is the right answer for **Not started**, **Live** and **Paused**. The middle four earn a number, because that is where an organization can quietly sit for months.

Put in your best guess today. Once the tool starts recording how long each rung *actually* takes — one of the things being built — you can replace the guess with the measured number. **An approximate clock beats no clock.**

The Jira token — done

Connected on a scoped read-only token. Kept for reference, and for the next person.

Connected

Your token is the **scoped read-only** kind — the better one, and the one you said was all this account could issue. It took a change to the program rather than a downgrade to your token, which was the right way round.

Nothing is configured yet, and that is expected. Test connection proves the credential; it saves nothing. Choosing which Jira fields carry the organization and the use case is a later sitting, and I will walk you through it.

- 1 Go to id.atlassian.com/manage-profile/security/api-tokens and choose **Create API token with scopes** — the read-only kind.
- 2 Tick **only the read ones** — the scopes beginning `read:`, for Jira work and Jira users. Nothing saying `write:`, `manage:` or `delete:`. The **label** Atlassian asks for is only a name on its own list and is used nowhere else.

The token appears **once**. Copy it somewhere safe before closing the page.

- 3 In Supabase: **Edge Functions** → **Secrets** → **Add new secret**. Do this **three times**. The **Name** must be typed exactly as printed here — it is not a label you choose:

```
JIRA_BASE_URL    https://your-site.atlassian.net
JIRA_EMAIL       the Atlassian account email
JIRA_API_TOKEN   the token from step 2
```

Three separate secrets, not one. Just the site in the URL — nothing after `.net`.

The mistake this step invites

The names on the left are **fixed**. The program looks for those three words and nothing else — give a secret any other name and it is invisible, however correct its value is. In particular **do not name a secret after the label you gave the token at Atlassian**; that label lives only on Atlassian's own list.

If Test connection says a secret is missing, this is almost always why. Go back to the secrets list and check the three names character for character.

- 4 **Wait for me to say the program is ready** — see the next page. Then in the app: **Settings** → **Jira** → **Test connection**.

Green, naming the account and site it signed in as. Red names exactly which of the three secrets is wrong — it never shows you the value.

Nothing is written to Jira, ever

The read-only guarantee here is **ours, not the token's**: the program can call four Jira addresses and no others, and its own tests check that by reading its source code, so a change that allowed writing would fail the build.

You get a preview of what it read and what it matched to; nothing changes on either side.

What that took, and why

Kept because it explains a trap that cost an evening, and the next person should not pay it again.

If you ever see “*Jira refused that email and token*” on a token you know is good, this is almost certainly why.

What is actually going on

A read-only scoped token is **only accepted at a different Jira address** from the ordinary one. Atlassian's own documentation:

```
You need to call the Atlassian API to use API tokens with scopes
for Jira https://api.atlassian.com/ex/jira/{cloudId}
```

The program used to call only your normal site address, so a scoped token was refused there — even though it was valid and the email was right. **It now looks up your site's cloud id and uses the other address automatically.**

Your settings stay exactly as they are

`JIRA_BASE_URL` is your normal site address, **not** the gateway one quoted above. The program works the rest out for itself, tries your site first, and only falls back to the gateway when a token needs it — so a different kind of token would still work tomorrow.

The mistake worth remembering

I first asked you to make a scoped token, then — when it was refused — asked you to downgrade to an unscoped one so my code could stay unchanged. That was the wrong trade, and you were right that this account could not do it anyway. **The fix belonged in the program.**

4

Hand out the sixteen codes

Ten minutes, and it is the only step with something you can lose.

All eighteen accounts exist. **Only you and Nasser have ever signed in** — checked live. The other sixteen are waiting for their codes.

- 1 Find the sixteen codes you copied out of Terminal when you ran the account step.
- 2 Give each person theirs directly — a message, in person, however you like. **Not in a group chat**, and not to me.
- 3 Tell them: go to <https://nphiescore.com/>, click **First time here?**, enter the code, choose a password.

They are in. Their username was fixed when the account was made and cannot be changed.

If you no longer have the codes

They exist nowhere else — not in a file, not in the database, not recoverable by me. That is deliberate. **Tell me and I will scrap and recreate the accounts that need it**, which prints fresh codes. It is cheap right now, while nobody is using them, and awkward once someone is.

Then check one screen

Settings → **Roles**. The two senior experts should hold **Director**; the three account managers stay **Member**. That split is what the whole permission design was built around — recording progress is the team's job, deciding shape and commitments is yours. Checked live, the roles are already right: two admins, seven Directors, nine Members.

5

Look at the new map

Fifteen minutes, when I send it. This is the step the whole rebuild is for.

I will send you **pictures first** — the new tree rendered at several sizes, in English and Arabic, on desktop and phone — before it is anywhere near your live site. Then a link you can click through.

Your job is to say what is wrong. Not to be polite about it. One sentence per thing is plenty, and “I don't know why but I don't like it” is a useful sentence — I can usually find the reason.

WHAT TO CHECK, IN ORDER

1

Can you see the shape of the programme? That is the job you gave the map. Open it and see whether the whole structure is legible at a glance — not one manager's corner of it.

2

Can you read the names? The old map drew hundreds of unlabelled dots. If any organization is a shape with no name, say so.

3

Does it look like your programme? The colour, the words, the density. Would you put this on a screen in front of a director?

4

Then Arabic, then your phone. Same questions. Arabic should be a mirror image, not a squeeze.

You will also get a settings screen for it

What each box shows, how big things are, how deep it opens, what drives the colour, how the branches are sorted. **With a live preview beside the controls**, so you can see a change as you make it rather than saving and hunting for it. If the shipped defaults are wrong for you, that screen is the fix — and telling me the defaults are wrong is also a useful sentence.

What I am building between your sittings

So the wait makes sense. This came out of benchmarking the tools a programme director will have used — Asana, Smartsheet, Wrike, Jira Align, Miro, XMind — against what you have.

The map itself

A vertical tree with real connectors and real names, that opens on the whole programme. It collapses, it searches, and it has a settings screen with a live preview.

Memory — the biggest gap, and it is invisible

Right now the tool records **where each organization is**, but not **where it has been**. So it cannot answer “are we moving faster than last month”, “how long does Testing actually take”, or “will we hit December” — even though your target dates are already stored. I am adding that memory. It starts recording the day it ships, so the sooner it lands the sooner the answers exist.

The three things a director would notice were missing

Search — typing a hospital's name and finding it on the map. **A stated red/amber/green with a reason**, beside the one the clock works out, so a manager who knows better can say so. **A go-live forecast** — the line of organizations live against your plan, and whether you will make the date.

And nothing goes near your live site until you say so

Every round is rendered and reviewed as pictures first. The live site keeps working exactly as it does now, the whole time.
